

MITOGENOME ANNOUNCEMENT

Characterization of the mitochondrial genome of the montane grasshopper, *Qinlingacris elaeodes* (Orthoptera: Catantopidae)

Abstract

Qinlingacris elaeodes is the dominant grasshopper at an altitude of 3000 meters and above, and is a representative species of the genus *Qinlingacris* endemic to China. The sequenced mitochondrial genome of this grasshopper is 14,818 bp in length, including 13 protein-coding genes (*ND1*-*6*, *COI*-*III*, *ATP6*, *ATP8*, *ND4L*, *CYTB*), 21 transfer RNAs, and 2 ribosomal RNAs (12S and 16S). The orientation and gene order of these genes are identical to those found in the putative ancestral insect mitogenome. The 13 PCGs start with a typical ATN codon as their start codons. The usual TAA and TAG termination codons are found for 12 PCGs. However, the *ND5* gene has an incomplete termination codon (T).

The genus *Qinlingacris* (Orthoptera: Catantopidae) is first published in 1979, and is endemic to Taibai Mountain in Shaanxi Province, China (Yin & Chou, 1979). To date, there are three known species within this genus (Li et al., 1991; Yin & Chou, 1979). *Qinlingacris elaeodes* is the dominant species at an altitude of 3000 meters and above, and is a representative species of the genus *Qinlingacris*.

At the last count, about fifty complete or nearly complete mitogenomes in Acridoidea species have been published in GenBank (<http://www.ncbi.nlm.nih.gov>, ending on August 30, 2014), among them only two species, *Shirakiacris shirakii* and

Kingdonella bicollina, belong to the Catantopidae. In this study, we described the characterization of mitogenome of *Q. elaeodes*. The adult specimens were collected in Shaanxi, China.

The nearly complete mitogenome sequence of the *Q. elaeodes* was 14,818 bp long, which comprised of 13 protein-coding genes (PCGs), 9 (*ND2*, *COI*, *COII*, *ATP8*, *ATP6*, *COIII*, *ND3*, *ND6* and *CYTB*) of them were distributed on the majority strand, while the rest (*ND5*, *ND4*, *ND4L*, *ND1*) were distributed on the minority strand. All of the PCGs in the *Q. elaeodes* mitogenome were initiated by typical ATN codons (eight with ATG, two with ATT, two with ATC and one with ATA). Twelve of 13 PCGs share the

Strand of the genes is presented as J for majority and N for minority strand. IN, negative numbers indicate that adjacent genes overlap, positive number indicate that intergenic sequences.

usual termination codon TAN (ten with TAA and two with TAG), and the remaining one PCG possesses the incomplete termination codons T for *ND5* gene (Table 1). The common interpretation of this phenomenon is that TAA termination was caused by posttranscriptional polyadenylation (Clary & Wolstenholme, 1985). The base composition in this mitogenome was: A = 42.6%, T = 33.1%, G = 10.4% and C = 13.9%. Although the A + T-rich region could not be amplified, the rate of A + T presented was also reaching a common level as high as the completely sequenced insect mitogenomes (Erler et al., 2010; Nardi et al., 2003).

Two ribosomal RNA genes (*rRNA*) were presented in *Q. elaeodes*. The length of the *16S* was 1314 bp, and the partial of *I2S* was 793 bp. Twenty-one transfer RNA genes (*tRNA*) varied from 64 bp (*tRNA^{Arg}*) to 71 bp (*tRNA^{Lys}*, *tRNA^{Ser}* and *tRNA^{Val}*) in size. The mitogenome of *Q. elaeodes* contained a total of 39 bp gene overlaps in 10 locations, the regions of which ranges from 1 to 8 bp in size. The length of the intergenic spacers varied from 1 to 22 bp. And the longest intergenic spacer was located between *tRNA^{Ser}* (*UCN*) and *ND1*.

The mitochondrial genes have been widely used as an informative molecular marker for diverse evolutionary studies of animals, including phylogenetics and population genetics. In this study, the mitogenome of *Q. elaeodes* was first analyzed. Therefore, we expect this mitogenome sequence to provide further insights into the phylogenetic relationships within and among families of the superfamily Acridoidea. What is more, it will provide more inspiration for us to study the movement differences and evolution of poly-type wings among the interesting grasshoppers.

Nucleotide sequence accession number

The mitogenome sequence of *Q. elaeodes* has been assigned GenBank accession number No. KM363599.
